FPGA design software that easily integrates into your design flow saves time and improves productivity. The Altera® Quartus® II software provides you with a command-line executable for each step of the FPGA design flow to make the design process customizable and flexible.

The benefits provided by command-line executables include:

- Command-line control over each step of the design flow
- Easy integration with scripted design flows including makefiles
- Reduced memory requirements
- Improved performance

The command-line executables are also completely interchangable with the Quartus II GUI, allowing you to use the exact combination of tools that you prefer.

This chapter describes how to take advantage of Quartus II command-line executables, and provides several examples of scripts that automate different segments of the FPGA design flow. This chapter includes the following topics:

- “Benefits of Command-Line Executables”
- “Introductory Example” on page 2-2
- “Compilation with quartus_sh --flow” on page 2-7
- “The MegaWizard Plug-In Manager” on page 2-11
- “Command-Line Scripting Examples” on page 2-17

**Benefits of Command-Line Executables**

The Quartus II command-line executables provide control over each step of the design flow. Each executable includes options to control commonly used software settings. Each executable also provides detailed, built-in help describing its function, available options, and settings.

Command-line executables allow for easy integration with scripted design flows. You can easily create scripts with a series of commands. These scripts can be batch-processed, allowing for integration with distributed computing in server farms. You can also integrate the Quartus II command-line executables in makefile-based design flows. These features enhance the ease of integration between the Quartus II software and other EDA synthesis, simulation, and verification software.
Command-line executables add flexibility without sacrificing the ease-of-use of the Quartus II GUI. You can use the Quartus II GUI and command-line executables at different stages in the design flow. For example, you might use the Quartus II GUI to edit the floorplan for the design, use the command-line executables to perform place-and-route, and return to the Quartus II GUI to perform debugging with the Chip Editor.

Command-line executables reduce the amount of memory required during each step in the design flow. Because each executable targets only one step in the design flow, the executables themselves are relatively compact, both in file size and the amount of memory used during processing. This memory usage reduction improves performance, and is particularly beneficial in design environments where heavy usage of computing resources results in reduced memory availability.

For a complete list of the Quartus II command-line executables, refer to Using the Quartus II Executables in Shell Scripts in Quartus II Help.

### Introductory Example

The following introduction to command-line executables demonstrates how to create a project, fit the design, and generate programming files.

The tutorial design included with the Quartus II software is used to demonstrate this functionality. If installed, the tutorial design is found in the `<Quartus II directory>/qdesigns/fir_filter` directory.

Before making changes, copy the tutorial directory and type the four commands shown in Example 2–1 at a command prompt in the new project directory.

![Image of a computer monitor with Quartus II software open]

**Example 2–1. Introductory Example**

```bash
quartus_map filtref --source=filtref.bdf --family="Cyclone III"
quartus_fit filtref --part=EP3C10F256C8 --pack_register=minimize_area
quartus_asm filtref
quartus_sta filtref
```

The `quartus_map filtref` command creates a new Quartus II project called `filtref` with `filtref.bdf` as the top-level file. It targets the Cyclone® III device family and performs logic synthesis and technology mapping on the design files.

The `quartus_fit filtref --part=EP3C10F256C8 --pack_register=minimize_area` command performs fitting on the `filtref` project. This command specifies an EP3C10F256C8 device, and the `--pack_register=minimize_area` option causes the Fitter to pack sequential and combinational functions into single logic cells to reduce device resource usage.

The `quartus_asm filtref` command creates programming files for the `filtref` project.

The `quartus_sta filtref` command performs basic timing analysis on the `filtref` project using the Quartus II TimeQuest Timing Analyzer, reporting worst-case setup slack, worst-case hold slack, and other measurements.
The TimeQuest Timing Analyzer employs Synopsys Design Constraints to fully analyze the timing of your design. For more information about using all of the features of the `quartus_sta` executable, refer to the TimeQuest Timing Analyzer Quick Start Tutorial.

You can put the four commands from Example 2–1 into a batch file or script file, and run them. For example, you can create a simple UNIX shell script called `compile.sh`, which includes the code shown in Example 2–2.

**Example 2–2. UNIX Shell Script: compile.sh**

```bash
#!/bin/sh
PROJECT=filtref
TOP_LEVEL_FILE=filtref.bdf
FAMILY="Cyclone III"
PART=EP3C10F256C8
PACKING_OPTION=minimize_area
quartus_map $PROJECT --source=$TOP_LEVEL_FILE --family=$FAMILY
quartus_fit $PROJECT --part=$PART --pack_register=$PACKING_OPTION
quartus_asm $PROJECT
quartus_sta $PROJECT
```

Edit the script as necessary and compile your project.

**Command-Line Scripting Help**

Help for command-line executables is available through different methods. You can access help built in to the executables with command-line options. You can use the Quartus II Command-Line and Tcl API Help browser for an easy graphical view of the help information.

To use the Quartus II Command-Line and Tcl API Help browser, type the following command:

```
quartus_sh --qhelp
```

This command starts the Quartus II Command-Line and Tcl API Help browser, a viewer for information about the Quartus II Command-Line executables and Tcl API (Figure 2–1).
Use the -h option with any of the Quartus II Command-Line executables to get a description and list of supported options. Use the --help=<option name> option for detailed information about each option.

**Figure 2–1. Quartus II Command-Line and Tcl API Help Browser**

**Project Settings with Command-Line Options**

Command-line options are provided for many common global project settings and for performing common tasks. You can use either of two methods to make assignments to an individual entity. If the project exists, open the project in the Quartus II GUI, change the assignment, and close the project. The changed assignment is updated in the .qsf. Any command-line executables that are run after this update use the updated assignment. For more information refer to “Option Precedence” on page 2–5. You can also make assignments using the Quartus II Tcl scripting API. If you want to completely script the creation of a Quartus II project, choose this method.

For more information about the Quartus II Tcl scripting API, refer to the Tcl Scripting chapter in volume 2 of the Quartus II Handbook. For more information about Quartus II project settings and assignments, refer to the QSF Reference Manual.
Option Precedence

If you use command-line executables, you must be aware of the precedence of various project assignments and how to control the precedence. Assignments for a particular project exist in the Quartus II Settings File (.qsf) for the project. Before the .qsf is updated after assignment changes, the updated assignments are reflected in compiler database files that hold intermediate compilation results.

All command-line options override any conflicting assignments found in the .qsf or the compiler database files. There are two command-line options to specify whether the .qsf or compiler database files take precedence for any assignments not specified as command-line options.

Any assignment not specified as a command-line option or found in the .qsf or compiler database file is set to its default value.

The file precedence command-line options are --read_settings_files and --write_settings_files.

By default, the --read_settings_files and --write_settings_files options are turned on. Turning on the --read_settings_files option causes a command-line executable to read assignments from the .qsf instead of from the compiler database files. Turning on the --write_settings_files option causes a command-line executable to update the .qsf to reflect any specified options, as happens when you close a project in the Quartus II GUI.

If you use command-line executables, be aware of the precedence of various project assignments and how to control the precedence. Assignments for a particular project can exist in three places:

- The .qsf for the project
- The result of the last compilation, in the /db directory, which reflects the assignments that existed when the project was compiled
- Command-line options

Table 2–1 lists the precedence for reading assignments depending on the value of the --read_settings_files option.

<table>
<thead>
<tr>
<th>Option Specified</th>
<th>Precedence for Reading Assignments</th>
</tr>
</thead>
</table>
| --read_settings_files = on | 1. Command-line options  
| (Default)                 | 2. The .qsf for the project  
|                           | 3. Project database (db directory, if it exists)  
|                           | 4. Quartus II software defaults                                      |
| --read_settings_files = off| 1. Command-line options  
|                            | 2. Project database (db directory, if it exists)  
|                            | 3. Quartus II software defaults                                      |
Table 2–2 lists the locations to which assignments are written, depending on the value of the --write_settings_files command-line option.

**Table 2–2. Location for Writing Assignments**

<table>
<thead>
<tr>
<th>Option Specified</th>
<th>Location for Writing Assignments</th>
</tr>
</thead>
<tbody>
<tr>
<td>--write_settings_files = on (Default)</td>
<td>.qsf and compiler database</td>
</tr>
<tr>
<td>--write_settings_files = off</td>
<td>Compiler database</td>
</tr>
</tbody>
</table>

Example 2–3 assumes that a project named fir_filter exists, and that the analysis and synthesis step has been performed (using the quartus_map executable).

**Example 2–3. Write Settings Files**

```
quartus_fit fir_filter --pack_register=off
quartus_sta fir_filter
mv fir_filter_sta.rpt fir_filter_1_sta.rpt
quartus_fit fir_filter --pack_register=minimize_area
   --write_settings_files=off
quartus_sta fir_filter
mv fir_filter_sta.rpt fir_filter_2_sta.rpt
```

The first command, quartus_fit fir_filter --pack_register=off, runs the quartus_fit executable with no aggressive attempts to reduce device resource usage.

The second command, quartus_sta fir_filter, performs basic timing analysis for the results of the previous fit.

The third command uses the UNIX mv command to copy the report file output from quartus_sta to a file with a new name, so that the results are not overwritten by subsequent timing analysis.

The fourth command runs quartus_fit a second time, and directs it to attempt to pack logic into registers to reduce device resource usage. With the --write_settings_files=off option, the command-line executable does not update the .qsf to reflect the changed register packing setting. Instead, only the compiler database files reflect the changed setting. If the --write_settings_files=off option is not specified, the command-line executable updates the .qsf to reflect the register packing setting.

The fifth command reruns timing analysis, and the sixth command renames the report file, so that it is not overwritten by subsequent timing analysis.

Use the options --read_settings_files=off and --write_settings_files=off (where appropriate) to optimize the way that the Quartus II software reads and updates settings files. In Example 2–4, the quartus_asm executable does not read or write settings files because doing so would not change any settings for the project.

**Example 2–4. Avoiding Unnecessary Reading and Writing**

```
quartus_map filtref --source=filtref --part=EP3C10F256C8
quartus_fit filtref --pack_register=off --read_settings_files=off
quartus_asm filtref --read_settings_files=off --write_settings_files=off
```
Compilation with `quartus_sh --flow`

Figure 2–2 shows a typical Quartus II FPGA design flow using command-line executables.

**Figure 2–2. Typical Design Flow**

Use the `quartus_sh` executable with the `-flow` option to perform a complete compilation flow with a single command. The `-flow` option supports the smart recompile feature and efficiently sets command-line arguments for each executable in the flow.

The following example runs compilation, timing analysis, and programming file generation with a single command:

```
quartus_sh --flow compile filtref
```

For information about specialized flows, type `quartus_sh --help=flow` at a command prompt.
Text-Based Report Files

Each command-line executable creates a text report file when it is run. These files report success or failure, and contain information about the processing performed by the executable.

Report file names contain the revision name and the short-form name of the executable that generated the report file, in the format `<revision>.<executable>.rpt`. For example, using the `quartus_fit` executable to place and route a project with the revision name `design_top` generates a report file named `design_top.fit.rpt`. Similarly, using the `quartus_sta` executable to perform timing analysis on a project with the revision name `fir_filter` generates a report file named `fir_filter.sta.rpt`.

As an alternative to parsing text-based report files, you can use the `::quartus::report` Tcl package. For more information about this package, refer to `::quartus::report` in Quartus II Help.

Using Command-Line Executables In Scripts

You can use command-line executables in scripts that control other software in addition to the Quartus II software. For example, if your design flow uses third-party synthesis or simulation software, and if you can run the other software at a command prompt, you can include those commands with Quartus II executables in a single script.

The Quartus II command-line executables include options for common global project settings and operations, but you must use a Tcl script or the Quartus II GUI to set up a new project and apply individual constraints, such as pin location assignments and timing requirements. Command-line executables are very useful for working with existing projects, for making common global settings, and for performing common operations. For more flexibility in a flow, use a Tcl script, which makes it easier to pass data between different stages of the design flow and have more control during the flow.

For more information about Tcl scripts, refer to the Tcl Scripting chapter in volume 2 of the Quartus II Handbook, or About Quartus II Tcl Scripting in Quartus II Help.
For example, a UNIX shell script could run other synthesis software, then place-and-route the design in the Quartus II software, then generate output netlists for other simulation software. Example 2–5 shows a script that synthesizes a design with the Synopsys Synplify software, simulates the design using the Mentor Graphics ModelSim® software, and then compiles the design targeting a Cyclone III device.

Example 2–5. Script for End-to-End Flow

```bash
#!/bin/sh
# Run synthesis first.
# This example assumes you use Synplify software
synplify -batch synthesize.tcl

# If your Quartus II project exists already, you can just
# recompile the design.
# You can also use the script described in a later example to
# create a new project from scratch
quartus_sh --flow compile myproject

# Use the quartus_sta executable to do fast and slow-model
# timing analysis
quartus_sta myproject --model=slow
quartus_sta myproject --model=fast

# Use the quartus_eda executable to write out a gate-level
# Verilog simulation netlist for ModelSim
quartus_eda my_project --simulation --tool=modelsim --format=verilog

# Perform the simulation with the ModelSim software
vlib cycloneiii_ver
vlog -work cycloneiii_ver /opt/quartusii/eda/sim_lib/cycloneiii_atoms.v
vlib work
vlog -work work my_project.vo
vsim -L cycloneiii_ver -t 1ps work.my_project
```

**Makefile Implementation**

You can use the Quartus II command-line executables in conjunction with the make utility to automatically update files when other files they depend on change. The file dependencies and commands used to update files are specified in a text file called a makefile.

To facilitate easier development of efficient makefiles, the following “smart action” scripting command is provided with the Quartus II software:

```
quartus_sh --determine_smart_action
```

Because assignments for a Quartus II project are stored in the .qsf, including it in every rule results in unnecessary processing steps. For example, updating a setting related to programming file generation, which requires re-running only quartus_asm, modifies the .qsf, requiring a complete recompilation if the .qsf is included in every rule.

The smart action command determines the earliest command-line executable in the compilation flow that must be run based on the current .qsf, and generates a change file corresponding to that executable. For example, if quartus_map must be re-run, the smart action command creates or updates a file named map.chg. Thus, rather than including the .qsf in each makefile rule, include only the appropriate change file.
Example 2–6 uses change files and the smart action command. You can copy and modify it for your own use. A copy of this example is included in the help for the makefile option, which is available by typing:

```
quartus_sh --help=makefiles
```

**Example 2–6. Sample Makefile (Part 1 of 2)**

```
# Project Configuration:
# Specify the name of the design (project), the Quartus II Settings
# File (.qsf), and the list of source files used.
PROJECT = chiptrip
SOURCE_FILES = auto_max.v chiptrip.v speed_ch.v tick_cnt.v time_cnt.v
ASSIGNMENT_FILES = chiptrip.qpf chiptrip.qsf

# Main Targets

# Executable Configuration

# Target implementations

$(PROJECT).map.rpt: map.chg $(SOURCE_FILES)
    quartus_map $(MAP_ARGS) $(PROJECT)
    $(STAMP) fit.chg
```

The MegaWizard Plug-In Manager

The MegaWizard™ Plug-In Manager provides a GUI-based flow to configure megafunction and IP variation files. However, you can use command-line options for the qmegawiz executable to modify, update, or create variation files without using the GUI. This capability is useful in a fully scripted design flow, or in cases where you want to generate variation files without using the wizard GUI flow.

The MegaWizard Plug-In Manager has three functions:

- Providing an interface for you to select the output file or files
- Running a specific MegaWizard Plug-In
- Creating output files (such as variation files, symbol files, and simulation netlist files)

Each MegaWizard Plug-In provides a user interface for configuring the variation, and performs validation and error checking of your selected ports and parameters. When you create or update a variation with the GUI, the parameters and values are entered through the GUI provided by the Plug-In. When you create a Plug-In variation with the command line, you provide the parameters and values as command-line options.

Example 2–7 shows how to create a new variation file at a system command prompt.

Example 2–7. MegaWizard Plug-In Manager Command-Line Executable

qmegawiz [options] [module=<module name>|wizard=<wizard name>]] [param=<value> ...] [port=<used|unused> ...] [OPTIONAL_FILES=<optional files>] <variation file name>

When you use qmegawiz to update an existing variation file, the module or wizard name is not required.
For more information on updating megafonction variation files as part of a scripted flow, refer to “Regenerating Megafonctions After Updating the Quartus II Software” on page 2–23.

Table 2–3 describes the supported options.

Table 2–3. qmegawiz Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-silent</td>
<td>Run the MegaWizard Plug-In Manager in command-line mode, without displaying the GUI.</td>
</tr>
<tr>
<td>-f: &lt;param file&gt;</td>
<td>A file that contains all options for the qmegawiz command. Refer to “Parameter File” on page 2–16.</td>
</tr>
</tbody>
</table>

For information about specifying the module name or wizard name, refer to “Module and Wizard Names” on page 2–13.

For information about specifying ports and parameters, refer to “Ports and Parameters” on page 2–14.

For information about generating optional files, refer to “Optional Files” on page 2–15.

For information about specifying the variation file name, refer to “Variation File Name” on page 2–17.

Command-Line Support

Only the MegaWizard Plug-Ins listed in Table 2–4 support creation and update in command-line mode. For Plug-Ins not listed in the table, you must use the MegaWizard Plug-In Manager GUI for creation and updates.

Table 2–4. MegaWizard Plug-Ins with Command Line Support (Part 1 of 2)

<table>

</tr>
</tbody>
</table>
You must specify the wizard or module name, shown in Table 2–4, as a command-line option when you create a variation file. Use the option module=<$module name$> to specify the module, or use the option wizard=<$wizard name$> to specify the wizard. If there are spaces in the wizard or module name, enclose the name in double quotes, for example:

```
wizard="RAM: 2-PORT"
```

When there is a one-to-one mapping between the MegaWizard Plug-In, the wizard name, and the module name, you can use either the wizard option or the module option.
When there are multiple wizard names that correspond to one module name, use the wizard option to specify one wizard. For example, use the wizard option if you create a RAM, because one module is common to three wizards.

When there are multiple module names that correspond to one wizard name, use the module option to specify one module. For example, use the module option if you create a FIFO because one wizard is common to both modules.

If you edit or update an existing variation file, the wizard or module option is not necessary, because information about the wizard or module is already in the variation file.

**Ports and Parameters**

Ports and parameters for each MegaWizard Plug-In are described in Quartus II Help, and in the *Megafunction User Guides* on the Altera website. Use these references to determine appropriate values for each port and parameter required for a particular variation configuration. Refer to “Strategies to Determine Port and Parameter Values” for more information. You do not have to specify every port and parameter supported by a Plug-In. The MegaWizard Plug-In Manager uses default values for any port or parameter you do not specify.

Specify ports as used or unused, for example:

```plaintext
<port>=used
<port>=unused
```

You can specify port names in any order. Grouping does not matter. Separate port configuration options from each other with spaces.

Specify a value for a parameter with the equal sign, for example:

```plaintext
<parameter>=<value>
```

You can specify parameters in any order. Grouping does not matter. Separate parameter configuration options from each other with spaces. You can specify port names and parameter names in upper or lower case; case does not matter.

All MegaWizard Plug-Ins allow you to specify the target device family with the `INTENDED_DEVICE_FAMILY` parameter, as shown in the following example:

```plaintext
qmegawiz wizard=<wizard> INTENDED_DEVICE_FAMILY="Cyclone III" <file>
```

You must specify enough ports and parameters to create a legal configuration of the Plug-In. When you use the GUI flow, each MegaWizard Plug-In performs validation and error checking for the particular ports and parameters you choose. When you use command-line options to specify ports and parameters, you must ensure that the ports and parameters you use are complete for your particular configuration.

For example, when you use a RAM Plug-In to configure a RAM to be 32 words deep, the Plug-In automatically configures an address port that is five bits wide. If you use the command-line flow to configure a RAM that is 32 words deep, you must use one option to specify the depth of the RAM, then calculate the width of the address port and specify that width with another option.
Invalid Configurations

If the combination of default and specified ports and parameters is not complete to create a legal configuration of the Plug-In, `qmegawiz` generates an error message that indicates what is missing and what values are supported. If the combination of default and specified ports and parameters results in an illegal configuration of the Plug-In, `qmegawiz` generates an error message that indicates what is illegal, and displays the legal values.

Strategies to Determine Port and Parameter Values

For simple Plug-In variations, it is often easy to determine appropriate port and parameter values with the information in Quartus II Help and other megafunction documentation. For example, determining that a 32-word-deep RAM requires an address port that is five bits wide is straightforward. For complex Plug-In variations, an option in the GUI might affect multiple port and parameter settings, so it can be difficult to determine a complete set of ports and parameters. In this case, use the GUI to generate a variation file that includes the ports and parameters for your desired configuration. Open the variation file in a text editor and use the port and parameter values in the variation file as command-line options.

Optional Files

In addition to the variation file, the MegaWizard Plug-In Manager can generate other files, such as instantiation templates, simulation netlists, and symbols for graphic design entry. Use the `OPTIONAL_FILES` parameter to control whether the MegaWizard Plug-In Manager generates optional files. Table 2–5 lists valid arguments for the `OPTIONAL_FILES` parameter.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INST</td>
<td>Controls the generation of the <code>&lt;variation&gt;_inst.v</code> file.</td>
</tr>
<tr>
<td>INC</td>
<td>Controls the generation of the <code>&lt;variation&gt;.inc</code> file.</td>
</tr>
<tr>
<td>CMP</td>
<td>Controls the generation of the <code>&lt;variation&gt;.cmp</code> file.</td>
</tr>
<tr>
<td>BSF</td>
<td>Controls the generation of the <code>&lt;variation&gt;.bsf</code> file.</td>
</tr>
<tr>
<td>BB</td>
<td>Controls the generation of the <code>&lt;variation&gt;_bb.v</code> file.</td>
</tr>
<tr>
<td>SIM_NETLIST</td>
<td>Controls the generation of the simulation netlist file, wherever there is wizard support.</td>
</tr>
<tr>
<td>SYNTH_NETLIST</td>
<td>Controls the generation of the synthesis netlist file, wherever there is wizard support.</td>
</tr>
<tr>
<td>ALL</td>
<td>Generates all applicable optional files.</td>
</tr>
<tr>
<td>NONE</td>
<td>Disables the generation of all optional files.</td>
</tr>
</tbody>
</table>

Specify a single optional file, for example:

```
OPTIONAL_FILES=<argument>
```

Specify multiple optional files separated by a vertical bar character, for example:

```
OPTIONAL_FILES=<argument 1>|...|<argument n>
```
If you prefix an argument with a dash (for example, -BB), it is excluded from the generated optional files. If any of the optional files exist when you run qmegawiz and they are excluded in the OPTIONAL_FILES parameter (with the NONE argument, or prefixed with a dash), they are deleted.

You can combine the ALL argument with other excluded arguments to generate “all files except <excluded files>.” You can combine the NONE argument with other included arguments to generate “no files except <files>.

When you combine multiple arguments, they are processed from left to right, and arguments evaluated later have precedence over arguments evaluated earlier. Therefore, use the ALL or NONE arguments first in a series of multiple arguments. When ALL is the first argument, all optional files are generated before exclusions are processed (deleted). When NONE is the first argument, none of the optional files are generated (in other words, any that exist are deleted), then any files you subsequently specify are generated.

Table 2–6 shows examples for the OPTIONAL_FILES parameter and describes the result of each example.

<table>
<thead>
<tr>
<th>Example Values for OPTIONAL_FILES</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BB</td>
<td>The optional file &lt;variation&gt;_bb.v is generated, and no optional files are deleted.</td>
</tr>
<tr>
<td>BB</td>
<td>INST</td>
</tr>
<tr>
<td>NONE</td>
<td>No optional files are generated, and any existing optional files are deleted.</td>
</tr>
<tr>
<td>NONE</td>
<td>INC</td>
</tr>
<tr>
<td>ALL</td>
<td>-INST</td>
</tr>
<tr>
<td>-BB</td>
<td>The optional file &lt;variation&gt;_bb.v is deleted if it exists.</td>
</tr>
<tr>
<td>-BB</td>
<td>INST</td>
</tr>
</tbody>
</table>

The qmegawiz command accepts the ALL argument combined with other included file arguments, for example, ALL|BB, but that combination is equivalent to ALL because first all optional files are generated, and then the file <variation>_bb.v is generated a second time. Additionally, the software accepts the NONE argument combined with other excluded file arguments, for example, NONE |-BB, but that combination is equivalent to NONE because no optional files are generated, any that exist are deleted, and then the file <variation>_bb.v is deleted if it exists.

**Parameter File**

You can put all parameter values and port values in a file, and pass the file name as an argument to qmegawiz with the -f:<parameter file> option. For example, the following command specifies a parameter file named rom_params.txt:

```
qmegawiz -silent module=altsyncram -f:rom_params.txt myrom.v
```

The rom_params.txt parameter file can include options similar to the following:
Working Directory

You can change the working directory that `qmegawiz` uses when it generates files. By default, the working directory is the current directory when you execute the `qmegawiz` command. Use the `-p` option to specify a different working directory, for example:

```
-p: <working directory>
```

You can specify the working directory with an absolute or relative path. Specify an alternative working directory any time you do not want files generated in the current directory. The alternative working directory can be useful if you generate multiple variations in a batch script, and keep generated files for the different Plug-In variations in separate directories.

If you use the `-f` option and the `-p` option together, the MegaWizard Plug-In Manager sources the parameter file in a directory specified with the `-p` option, or in a directory relative to that directory. For example, if you specify `C:\project\work` with the `-p` option and `work\params.txt` with the `-f` option, the MegaWizard Plug-In Manager attempts to source the file `params.txt` in `C:\project\work\work`.

Variation File Name

The language used for a variation file depends on the file extension of the variation file name. The MegaWizard Plug-In Manager creates HDL output files in a language based on the file name extension. Therefore, you must always specify a complete file name, including file extension, as the last argument to the `qmegawiz` command. Table 2–7 shows the file extension that corresponds to supported HDL types.

<table>
<thead>
<tr>
<th>Variation File HDL Type</th>

</table>

Command-Line Scripting Examples

This section presents various examples of command-line executable use.

Create a Project and Apply Constraints

The command-line executables include options for common global project settings and commands. To apply constraints such as pin locations and timing assignments, run a `Tcl` script with the constraints in it. You can write a `Tcl` constraint file yourself, or generate one for an existing project. From the Project menu, click Generate `Tcl File for Project`. 

RAM_BLOCK_TYPE=M4K DEVICE_FAMILY=Stratix WIDTH_A=5 WIDTHAD_A=5 NUMWORDS_A=32 INIT_FILE=rom.hex OPERATION_MODE=ROM
Example 2–8 creates a project with a Tcl script and applies project constraints using the tutorial design files in the `<Quartus II installation directory>/qdesigns/fir_filter/` directory.

**Example 2–8. Tcl Script to Create Project and Apply Constraints**

```tcl
project_new filtref -overwrite
# Assign family, device, and top-level file
set_global_assignment -name FAMILY Cyclone
set_global_assignment -name DEVICE EP1C12F256C6
set_global_assignment -name BDF_FILE filtref.bdf
# Assign pins
set_location_assignment -to clk Pin_28
set_location_assignment -to clkx2 Pin_29
set_location_assignment -to d[0] Pin_139
set_location_assignment -to d[1] Pin_140
# Other assignments could follow
project_close
```

Save the script in a file called `setup_proj.tcl` and type the commands illustrated in Example 2–9 at a command prompt to create the design, apply constraints, compile the design, and perform fast-corner and slow-corner timing analysis. Timing analysis results are saved in two files, `filtref_sta_1.rpt` and `filtref_sta_2.rpt`.

**Example 2–9. Script to Create and Compile a Project**

```bash
quartus_sh -t setup_proj.tcl
quartus_map filtref
quartus_fit filtref
quartus_asm filtref
quartus_sta filtref --model=fast --export_settings=off
mv filtref_sta.rpt filtref_sta_1.rpt
mv filtref_sta.rpt filtref_sta_2.rpt
```

Type the following commands to create the design, apply constraints, and compile the design, without performing timing analysis:

```bash
quartus_sh -t setup_proj.tcl
quartus_sh --flow compile filtref
```

The `quartus_sh --flow compile` command performs a full compilation, and is equivalent to clicking the **Start Compilation** button in the toolbar.

**Check Design File Syntax**

The UNIX shell script example shown in Example 2–10 assumes that the Quartus II software `fir_filter` tutorial project exists in the current directory. You can find the `fir_filter` project in the `<Quartus II directory>/qdesigns/fir_filter` directory unless the Quartus II software tutorial files are not installed.

The `--analyze_file` option causes the `quartus_map` executable to perform a syntax check on each file. The script checks the exit code of the `quartus_map` executable to determine whether there is an error during the syntax check. Files with syntax errors are added to the `FILES_WITH_ERRORS` variable, and when all files are checked, the script prints a message indicating syntax errors.
When options are not specified, the executable uses the project database values. If not specified in the project database, the executable uses the Quartus II software default values. For example, the fir_filter project is set to target the Cyclone device family, so it is not necessary to specify the --family option.

Example 2–10. Shell Script to Check Design File Syntax

```bash
#!/bin/sh
FILES_WITH_ERRORS=""
# Iterate over each file with a .bdf or .v extension
for filename in `ls *.bdf *.v`
do
    # Perform a syntax check on the specified file
    quartus_map fir_filter --analyze_file=$filename
    # If the exit code is non-zero, the file has a syntax error
    if [ $? -ne 0 ]
        then FILES_WITH_ERRORS="$FILES_WITH_ERRORS $filename"
    fi
done
if [ -z "$FILES_WITH_ERRORS" ]
    then echo "All files passed the syntax check"
        exit 0
else
    echo "There were syntax errors in the following file(s)"
    echo $FILES_WITH_ERRORS
    exit 1
fi
```

Create a Project and Synthesize a Netlist Using Netlist Optimizations

This example creates a new Quartus II project with a file top.edf as the top-level entity. The --enable_register_retiming=on and --enable_wysiwyg_resynthesis=on options cause quartus_map to optimize the design using gate-level register retiming and technology remapping.

For more information about register retiming, WYSIWYG primitive resynthesis, and other netlist optimization options, refer to Quartus II Help.

The --part option causes quartus_map to target an EP3C10F256C8 device. To create the project and synthesize it using the netlist optimizations described above, type the command shown in Example 2–11 at a command prompt.

Example 2–11. Creating a Project and Synthesizing a Netlist Using Netlist Optimizations

```bash
quartus_map top --source=top.edf --enable_register_retiming=on --enable_wysiwyg_resynthesis=on --part=EP3C10F256C8
```
**Archive and Restore Projects**

You can archive or restore a Quartus II Archive File (.qar) with a single command. This makes it easy to take snapshots of projects when you use batch files or shell scripts for compilation and project management. Use the `--archive` or `--restore` options for `quartus_sh` as appropriate. Type the command shown in Example 2–12 at a command prompt to archive your project.

**Example 2–12. Archiving a Project**

```plaintext
quartus_sh --archive <project name>
```

The archive file is automatically named `<project name>.qar`. If you want to use a different name, type the command with the `-output` option as shown in example Example 2–13.

**Example 2–13. Archiving a Project**

```plaintext
quartus_sh --archive <project name> -output <filename>
```

To restore a project archive, type the command shown in Example 2–14 at a command prompt.

**Example 2–14. Restoring a Project Archive**

```plaintext
quartus_sh --restore <archive name>
```

The command restores the project archive to the current directory and overwrites existing files.

For more information about archiving and restoring projects, refer to the Managing Quartus II Projects chapter in volume 2 of the Quartus II Handbook.

**Perform I/O Assignment Analysis**

You can perform I/O assignment analysis with a single command. I/O assignment analysis checks pin assignments to ensure they do not violate board layout guidelines. I/O assignment analysis does not require a complete place and route, so it can quickly verify that your pin assignments are correct. The command shown in Example 2–15 performs I/O assignment analysis for the specified project and revision.

**Example 2–15. Performing I/O Assignment Analysis**

```plaintext
quartus_fit --check_ios <project name> --rev=<revision name>
```

**Update Memory Contents Without Recompiling**

You can use two commands to update the contents of memory blocks in your design without recompiling. Use the `quartus_cdb` executable with the `--update_mif` option to update memory contents from `.mif` or `.hexout` files. Then, rerun the assembler with the `quartus_asm` executable to regenerate the `.sof`, `.pof`, and any other programming files.
Example 2–16 shows these two commands.

**Example 2–16. Commands to Update Memory Contents Without Recompiling**

```bash
quartus_cdb --update_mif <project name> [--rev=<revision name>]
quartus_asm <project name> [--rev=<revision name>]
```

Example 2–17 shows the commands for a DOS batch file for this example. With a DOS batch file, you can specify the project name and the revision name once for both commands. To create the DOS batch file, paste the following lines into a file called `update_memory.bat`.

**Example 2–17. Batch file to Update Memory Contents Without Recompiling**

```bash
quartus_cdb --update_mif %1 --rev=%2
quartus_asm %1 --rev=%2
```

To run the batch file, type the following command at a command prompt:

`update_memory.bat <project name> <revision name>`

### Create a Compressed Configuration File

You can create a compressed configuration file in two ways. The first way is to run `quartus_cpf` with an option file that turns on compression.

To create an option file that turns on compression, type the following command at a command prompt:

```bash
quartus_cpf -w <filename>.opt
```

This interactive command guides you through some questions, then creates an option file based on your answers. Use `--option` to cause `quartus_cpf` to use the option file. For example, the following command creates a compressed `.pof` that targets an EPCS64 device:

```bash
quartus_cpf --convert --option=<filename>.opt --device=EPCS64 <file>.sof <file>.pof
```

Alternatively, you can use the Convert Programming Files utility in the Quartus II software GUI to create a Conversion Setup File (.cof). Configure any options you want, including compression, then save the conversion setup. Use the following command to run the conversion setup you specified.

```bash
quartus_cpf --convert <file>.cof
```

### Fit a Design as Quickly as Possible

This example assumes that a project called `top` exists in the current directory, and that the name of the top-level entity is `top`. The `--effort=fast` option causes the `quartus_fit` to use the fast fit algorithm to increase compilation speed, possibly at the expense of reduced \( f_{\text{MAX}} \) performance. The `--one_fit_attempt=on` option restricts the Fitter to only one fitting attempt for the design.
To attempt to fit the project called \texttt{top} as quickly as possible, type the command shown in Example 2–18 at a command prompt.

**Example 2–18. Fitting a Project Quickly**

```
quartus_fit top --effort=fast --one_fit_attempt=on
```

**Fit a Design Using Multiple Seeds**

This shell script example assumes that the Quartus II software tutorial project called \texttt{fir\_filter} exists in the current directory (defined in the file \texttt{fir\_filter.qpf}). If the tutorial files are installed on your system, this project exists in the \texttt{<Quartus II directory>/qdesigns\_<quartus\_version\_number>/fir\_filter} directory. Because the top-level entity in the project does not have the same name as the project, you must specify the revision name for the top-level entity with the \texttt{--rev} option. The \texttt{--seed} option specifies the seeds to use for fitting.

A seed is a parameter that affects the random initial placement of the Quartus II Fitter. Varying the seed can result in better performance for some designs.

After each fitting attempt, the script creates new directories for the results of each fitting attempt and copies the complete project to the new directory so that the results are available for viewing and debugging after the script has completed.

**Example 2–19** is designed for use on UNIX systems using \texttt{sh} (the shell).

**Example 2–19. Shell Script to Fit a Design Using Multiple Seeds**

```
#!/bin/sh
ERROR_SEEDS=""
quartus_map fir\_filter --rev=filtref
# Iterate over a number of seeds
for seed in 1 2 3 4 5
  do
    echo "Starting fit with seed=$seed"
    # Perform a fitting attempt with the specified seed
    quartus_fit fir\_filter --seed=$seed --rev=filtref
    # If the exit-code is non-zero, the fitting attempt was successful, so copy the project to a new directory
    if [ $? -eq 0 ]
      then
        mkdir ../fir\_filter\_seed\_$seed
        mkdir ../fir\_filter\_seed\_$seed/db
        cp * ../fir\_filter\_seed\_$seed
        cp db/* ../fir\_filter\_seed\_$seed/db
      else
        ERROR_SEEDS="$ERROR_SEEDS $seed"
    fi
  done
if [ -z "$ERROR_SEEDS" ]
  then
    echo "Seed sweeping was successful"
    exit 0
  else
    echo "There were errors with the following seed(s)"
    echo $ERROR_SEEDS
    exit 1
  fi
```
Use the Design Space Explorer (DSE) included with the Quartus II software script (by typing `quartus_sh --dse` at a command prompt) to improve design performance by performing automated seed sweeping.

For more information about the DSE, type `quartus_sh --help=dse` at a command prompt, or refer to `Design Space Explorer` in Quartus II Help.

### Regenerating MegafUNCTIONs After Updating the Quartus II Software

Some megafuction variations may require regeneration when you update your installation of the Quartus II software. Read the release notes for the Quartus II software and any new documentation for the IP functions used in your design to determine if regeneration is necessary.

If regeneration is necessary, you can use a Tcl script to run the `qmegawiz` executable to update each function, allowing you to avoid regenerating each function in the Megawizard Plug-In Manager GUI.

Wizard-generated files are identified in the Source Files Used report panel (contained in `<project name>.map.rpt`) in the File Type column as “Auto-Found Wizard-Generated File”. In a Tcl script, use the commands in the `::quartus::report` package from the Quartus II Tcl API to recover the list of files. Use the `qexec` command in a loop to run `qmegawiz` for each variation file:

```
qexec "qmegawiz -silent <variation file name>"
```

For example, if your script determines that your design contains a variation file called `myrom.v`, in one iteration of the loop in your script, a combination of strings and variables passed to the `qexec` command would be equivalent to the following command:

```
qexec "qmegawiz -silent myrom.v"
```

If your design flow incorporates parameter files, those can be included in the `qmegawiz` call in the same way you would include them from a command prompt:

```
qexec "qmegawiz -silent -f:<parameter file>.txt <variation file name>"
```

For more information about the `::quartus::report` Tcl package, refer to `::quartus::report` in Quartus II Help.

For more information about the Quartus II Tcl scripting API, refer to the `Tcl Scripting` chapter in volume 2 of the `Quartus II Handbook`.

### The QFlow Script

A Tcl/Tk-based graphical interface called QFlow is included with the command-line executables. You can use the QFlow interface to open projects, launch some of the command-line executables, view report files, and make some global project assignments. The QFlow interface can run the following command-line executables:

- `quartus_map` (Analysis and Synthesis)
- `quartus_fit` (Fitter)
- `quartus_sta` (TimeQuest timing analyzer)
- quartus_asm (Assembler)
- quartus_eda (EDA Netlist Writer)

To view floorplans or perform other GUI-intensive tasks, launch the Quartus II software.

Start QFlow by typing the following command at a command prompt:
```
quartus_sh -g
```

The QFlow script is located in the `<Quartus II directory>/common/tcl/apps/qflow/` directory.

### Document Revision History

Table 2–8 shows the revision history for this chapter.

<table>
<thead>
<tr>
<th>Date</th>
